UNIT 7

Streams

KNOWLEDGE IS THE CURRENCY
FOR THE 21st CENTURY

Objective of this Unit

- Concept of Stream
- C++ Stream Classes
- Formatted and unformatted I/O operations
- Manipulators

Concept Of stream

Managing console I/O operation

- C++ uses the concept of stream and stream classes to implement its I/O operations with the console and disk files.
- C++ supports all of C's rich set of I/O functions.
- **Stream is a general name given to a flow of data.**

C++ Stream

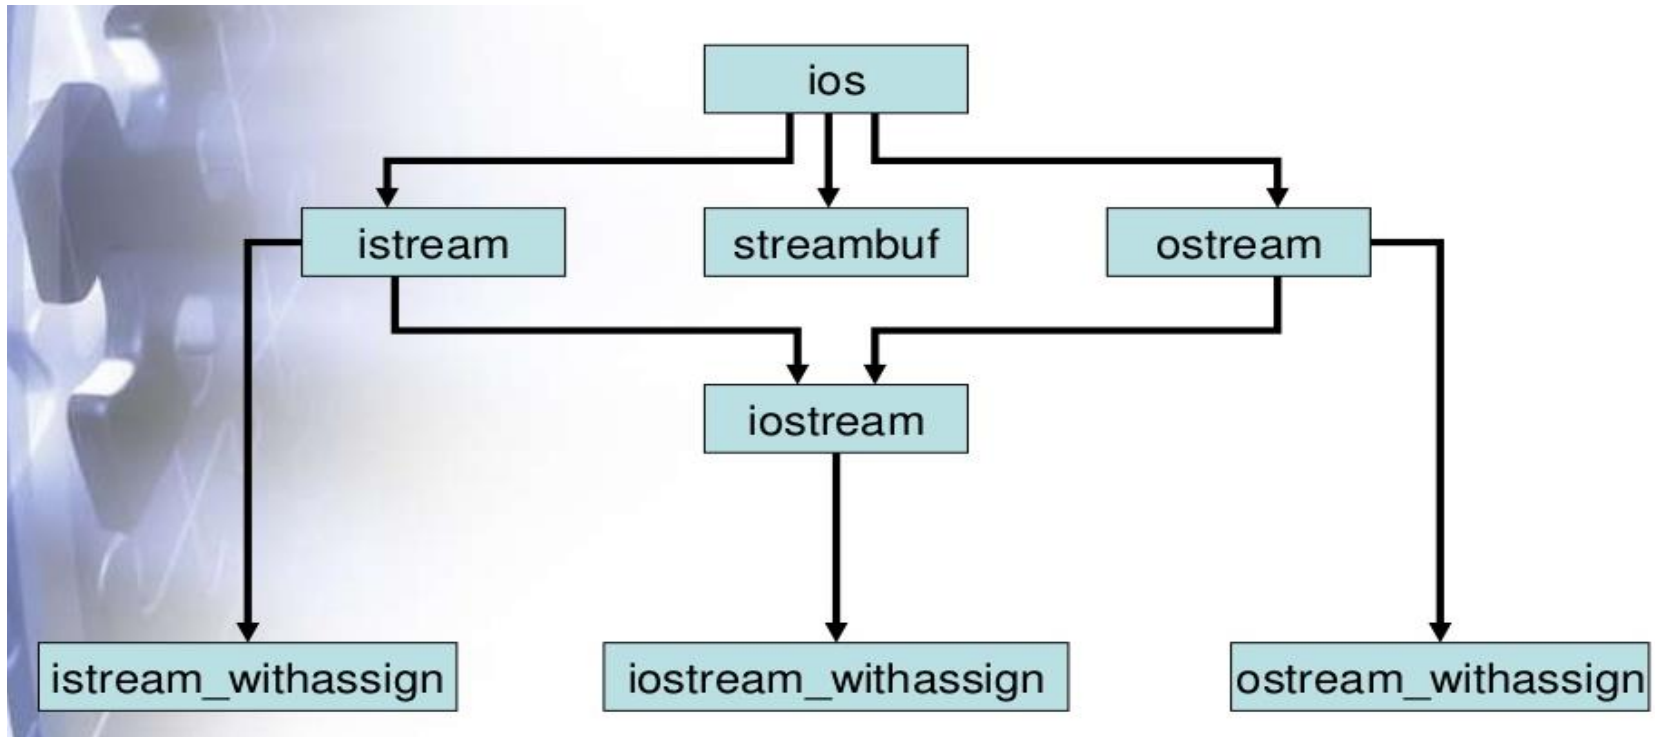

- Stream is an interface supplied by the I/O system of C++ between the programmer and the actual device being accessed.
- It will work with devices like terminals, disks and tape drives.
- **A stream is a sequence of bytes.**
- It acts either as a source from which the input data can be obtained or as a destination to which the output data can be sent.

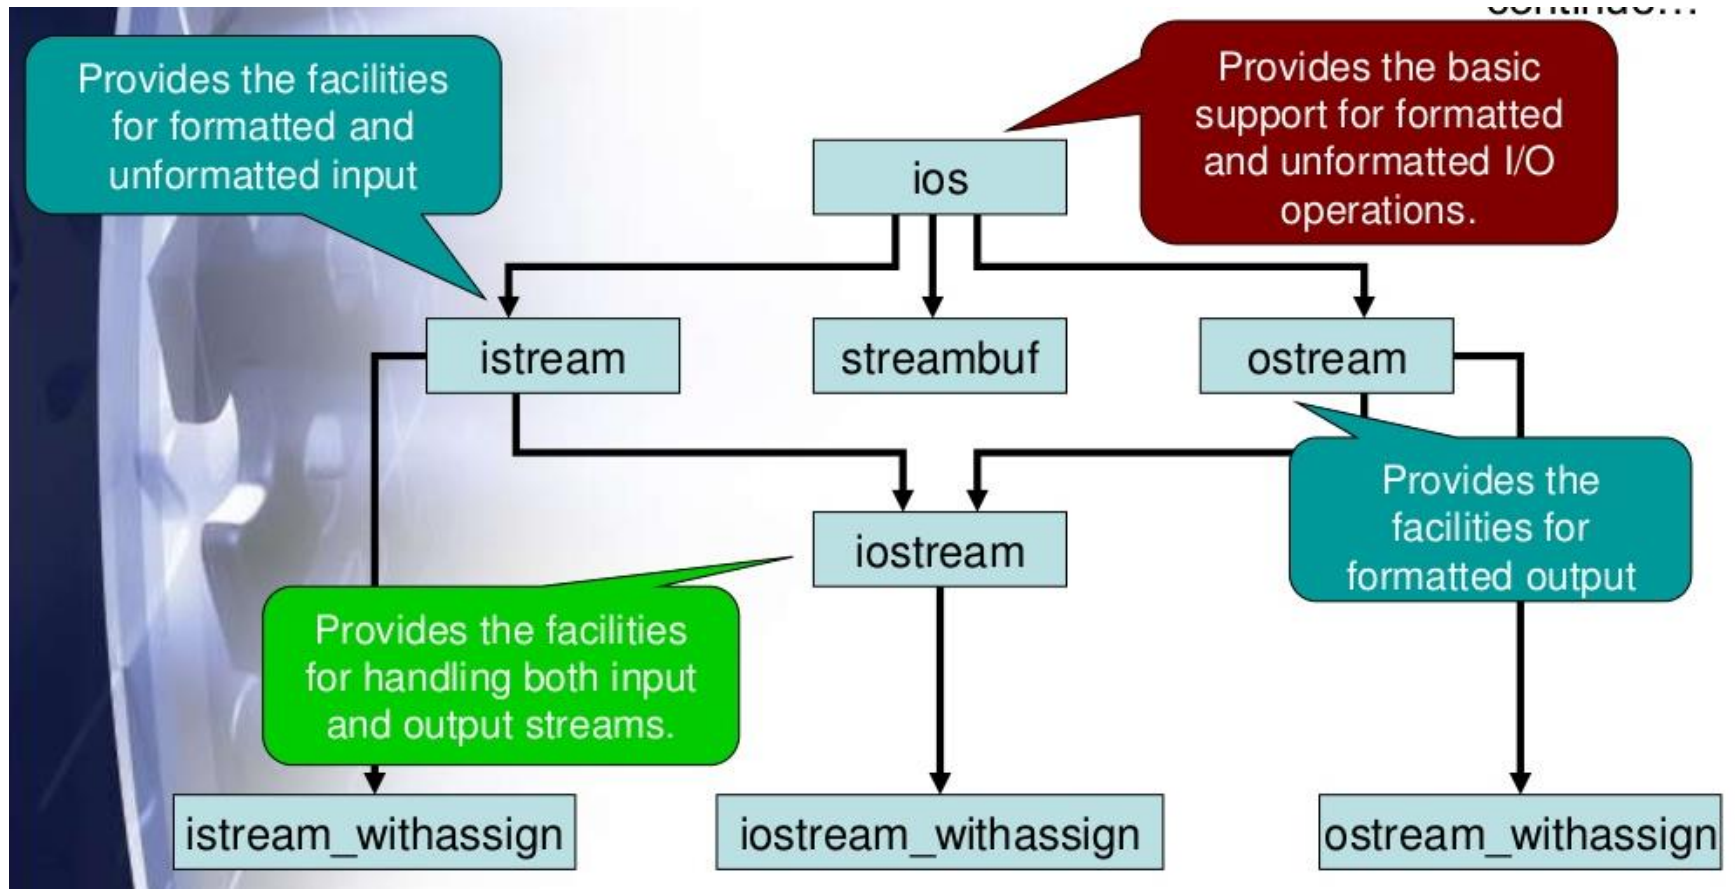

- **Input Stream:-** The Source that provides data to the program.
- **Output Stream:-** The destination streams that receives output from the program.
- The data in the input stream can come **from keyboard** or any other storage device.
- The data in the output stream can go to the **screen** or any other **storage devices**.

C++ stream Classes

- The C++ I/O system contains a hierarchy of classes that are used to define various streams to deal with both the console and disk files.
- These classes are called stream classes.
- These classes are declared in the header file `iostream`.

Unformatted I/O Operations

Overloaded Operators >> and <<

- The objects cin and cout are used for input and output of data of various types.

By overloading the operators >> and <<

- >> operator is overloaded in the istream class.
- << operator is overloaded in the ostream class.
- This is used for input data through keyboard.
- `cin>>var1>>var2.....>>varN`
(where var1,var2,...,varN are valid variable name)
- `cout<<item1<<item2....<<itemN`
(where item1,item2....itemN may be variables or constants of a basic type)

Unformatted I/O Operations

- **put() and get() Functions**
 - get() and put() are member functions of istream and ostream classes.
 - For single character input/output operations.
 - There two types of get() functions:
 - get(char *) :-Assigns the input character to its argument
 - get(void) :-Returns the input character
- ```
char c;
cin.get(c);
c=cin.get();
```
- put():-used to output a line of text, character by character.

```
char c;
cout.put('x');
cout.put(c);
```

# Unformatted I/O Operations

- **getline() and write() functions**
- **getline()** function reads a whole line of text that ends with a newline character. The new line character is read but not saved.
- `cin.getline(line,size);`
- Reading is terminated as soon as either the newline character ‘\n’ is encountered or size-1 characters are read.
- **write()** function displays an entire line of text.
- `cout.write(line,size);`
- `write()` also used to concatenate strings.

# Formatted console I/O Operations

- C++ supports a number of features that could be used for formatting the output,
- These features include:
  - ios class functions and flags.
  - Manipulators.
  - User-defined output functions.

# ios member functions

- **width()** :- To specify the required field size for displaying an output value.
- **precision()** :- To specify the number of digits to be displayed after the decimal point of a float value.
- **fill()** :-To specify a character that is used to fill the unused portion of a field.
- **setf()** :-To specify format flags that can control the form of output display.
- **unsetf()** :-To clear the flags specified.

# Manipulators

- **Manipulators** are special functions that can be included in the I/O statement to alter the format parameters of a stream.
- To access manipulators, the file **iomanip.h** should be included in the program.
  - setw()
  - setprecision()
  - setfill()
  - setiosflags()
  - resetiosflags()

# width() :-Defining Field width

- To define the width of a field necessary for the output of an item.
- Since it is a member function, we have to use an object to invoke it.

`cout.width(w)` ,Where w is the field width(number of columns).

- The output will be printed in a field of w character wide at the right end of the field.
- The `width()` function can specify the field width for only one item-item that follows immediately.

```
cout.width(5);
cout << 543 << 12 << "\n";
```

|  |  |   |   |   |   |   |
|--|--|---|---|---|---|---|
|  |  | 5 | 4 | 3 | 1 | 2 |
|--|--|---|---|---|---|---|

```
cout.width(5);
cout << 543;
cout.width(5);
cout << 12 << "\n";
```

The field should be specified for each item separately.

|  |  |   |   |   |  |  |  |   |   |
|--|--|---|---|---|--|--|--|---|---|
|  |  | 5 | 4 | 3 |  |  |  | 1 | 2 |
|--|--|---|---|---|--|--|--|---|---|

# precision() :-Setting Precision

- Used to specify the number of digits to be displayed after the decimal point while printing the floating-point numbers.
- By default, the floating numbers are printed six digits after the decimal point.

- `cout.precision(d);`
  - *Where d is the number of digits to the right of the decimal point.*

```
cout.precision(3);
cout << sqrt(2) << endl;
cout << 3.14159 << endl;
cout << 2.50032 << endl;
```

|       |                    |
|-------|--------------------|
| 1.141 | → truncated        |
| 3.142 | → rounded          |
| 2.5   | → 0 trailing zeros |

# precision() :-Setting Precision

- Unlike width(), precision() retains the setting in effect until it is reset.
- We can also combine the field specification with the precision setting.

```
cout.precision(2);
cout.width(5);
cout << 1.2345;
```

|  |   |   |   |   |
|--|---|---|---|---|
|  | 1 | . | 2 | 3 |
|--|---|---|---|---|

# fill() :-Filling and padding

- When printing values with larger field width then required by the values, the unused positions of the field are filled with white spaces, by default.
- fill() function can be used to fill the unused positions by any desired character.

```
cout.fill(ch);
where ch represents the character which is
used for filling the unused positions.
cout.fill(' * ');
cout.width(10);
cout << 5250 << endl;
```

Like precision( ), fill( ) stays in effect till we change it.

|   |   |   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|---|---|
| * | * | * | * | * | * | 5 | 2 | 5 | 0 |
|---|---|---|---|---|---|---|---|---|---|

# setf() :-formatting flags, bit-fields

- When the function width() is used, the value will be printed right-justified in the created width.
- setf() function is used to print values in left-justified.

- `cout.setf(arg1, arg2)`

eg:

```
cout.fill(' *');
```

```
cout.setf(ios :: left, ios :: adjustfield);
```

```
cout.width(10);
```

```
cout << "TABLE 1" << endl;
```

**arg1** is formatting flags defined in the class ios and **arg2** is bit field constant in the ios class.

|   |   |   |   |   |  |   |   |   |   |
|---|---|---|---|---|--|---|---|---|---|
| T | A | B | L | E |  | 1 | * | * | * |
|---|---|---|---|---|--|---|---|---|---|

# setf() :-formatting flags, bit-fields

- When the function width( ) is used, the value ...

The formatting flag specifies the format action required for the output.

Bit field specifies the group to which the formatting flag belongs.

- `cout.setf(arg1, arg2)`  
eg:  
`cout.fill(' * ');`  
`cout.setf(ios :: left, ios :: adjustfield);`  
`cout.width(10);`  
`cout << "TABLE 1" << endl;`

**arg1** is formatting flags defined in the class ios and **arg2** is bit field constant in the ios class.

|   |   |   |   |   |  |   |   |   |   |
|---|---|---|---|---|--|---|---|---|---|
| T | A | B | L | E |  | 1 | * | * | * |
|---|---|---|---|---|--|---|---|---|---|

# Managing output with Manipulators

- The header file `iomanip` provides a set of functions called manipulators which can be used to manipulate the output formats.
- Some manipulators are more convenient to use the member functions and flags of `ios`.
- Two or more manipulators can be used as a chain in one statement.

```
cout<<manip1<<manip2<<manip3<<item;
```

```
cout<<manip1<<item1<<manip2<<item2;
```

# Managing output with manipulators

- Manipulators and their meanings

| Manipulators                     | Meaning                           | Equivalent                |
|----------------------------------|-----------------------------------|---------------------------|
| <code>setw(int w)</code>         | Set the field width to w          | <code>width( )</code>     |
| <code>setprecision(int d)</code> | Set floating point precision to d | <code>precision( )</code> |
| <code>setfill( int c)</code>     | Set the fill character to c       | <code>fill( )</code>      |

```
cout << setw(5) << setprecision(2) << 1.2345
 << setw(10) << setprecision(4) << sqrt(2);
```

- We can jointly use the manipulators and the ios functions in a program.

# Manipulators & ios member function

- The ios member function return the previous format state which can be used later.
- But the manipulator does not return the previous format state.

```
cout.precision(2); // previous state.
int p =cout.precision(4); // current state, p=2.
cout.precision(p); // change to previous state
```

# Designing our own Manipulators

- We can design our own manipulators for certain special purpose.

```
ostream & manipulator (ostream & output)
{
 (code)
 return output;
}

ostream & unit (ostream & output)
{
 output << "inches";
 return output;
}

cout << 36 << unit; → will produce "36 inches".
```

# Designing our own Manipulators

- We can also create manipulators that could represent a sequence of operations:

```
ostream & show (ostream & output)
{
 output.setf(ios::showpoint);
 output.setf(ios::showpos);
 output << setw(10);
 return output;
}
```

- This function defines a manipulator called show that turns on the flags showpoint and showpos declared in the class ios and sets the field width to 10.

*Thank You*
